

The four layers are four different objects

Ties in the layer

Mean degree

Bipartite is person → cabinet; co-membership is served together; succession is same portfolio, directed; homophily is a shared attribute. Counts are not a ranking: co-membership dominates by construction, since every pair in a cabinet is a tie and it grows with the square of cabinet size, while succession grows linearly with handovers. The bipartite layer is the primitive the other three derive from; its node count includes cabinets as well as people.
